Abstract—The multi-user Holographic Multiple-Input and Multiple-Output Surface (MU-HMIMOS) paradigm, which is capable of realizing large continuous apertures with minimal power consumption, has been recently considered as an energy-efficient solution for future wireless networks, offering increased flexibility in impacting electromagnetic (EM) wave propagation according to the desired communication, localization, and sensing objectives. The tractable channel modeling in MU-HMIMOS wireless systems is one of the most critical research challenges, mainly due to the coupling effect induced by the excessively large number of closely spaced patch antennas. In this paper, we focus on this challenge for the downlink of multi-user MIMO communications and extend an EM-compliant channel model to multi-user case, which is expressed in the wavenumber domain using the Fourier plane wave approximation. Based on the presented channel model, we

investigate the spectral efficiency of maximum-ratio transmission and Zero-Forcing (ZF) precoding schemes. We also introduce a novel hardware efficient ZF precoder, leveraging Neumann series (NS) expansion to replace the required matrix inversion operation, which is very hard to be computed in the conventional way due to the extremely large number of patch antennas in the envisioned MU-HMIMOS communication systems. In comparison with the conventional independent and identical Rayleigh fading channels that ignore antenna coupling effects, the proposed EM-compliant channel model captures the mutual couplings induced by the very small antenna spacing. Our extensive performance evaluation results demonstrate that our theoretical performance expressions approximate sufficiently well the simulated achievable spectral efficiency with the considered linear precoding schemes, even for the highly correlated cases, thus verifying the effectiveness and robustness of the presented analytical framework. In addition, it is verified that the proposed NS-based ZF precoder achieves similar performance to conventional ZF, while requiring lower hardware complexity, thus, providing a hardware efficient solution for practical design of MU-HMIMOS communications systems.

Index Terms—Channel modeling, holographic MIMO surface, multi-user communications, spectral efficiency, Neumann series expansion, wave propagation control.

I. INTRODUCTION

IN RECENT years, the demands for ubiquitous wireless communications are rapidly growing due to the explosive development of mobile devices and multimedia applications (including extending reality) [1]. To satisfy those needs and requirements, the exploitation of the ultimate limits of wireless communication approaches is mandatory, in conjunction with the introduction and optimization of novel technologies providing larger bandwidths and improved energy efficiency, e.g., TeraHertz (THz) [2] and millimeter-Wave (mmWave) communications [3], as well as extreme Multiple-Input Multiple-Output (MIMO) catering for massive users and throughput [4], [5]. However, more profound requirements for data rate and massive connections are lately put forward for 6-th Generation (6 G) wireless communications. In addition, the large available bandwidth at higher frequencies does not come for free, imposing several algorithmic and hardware design challenges.

In MIMO systems, a Base Station (BS) equipped with multiple antenna elements serves a single or multiple users via spatial multiplexing [6]–[12]. Techniques falling into this category are capable of improving Spectral Efficiency (SE), by increasing the number of antennas and/or the users. The massive MIMO version, which has been recently adopted in the 5-th Generation

(5 G) New Radio (NR), utilizes very large antenna arrays at the BS to serve multiple single-antenna users with simple beam-forming, yielding boosted rate performance [13]. In fact, even when the number of BS antennas grows large, the overall power consumption is kept fixed SE improves [14]. In [15], the authors showcased that the hardware distortion in massive MIMO has negligible impact on the achievable SE performance. In [16], a cooperative Non-Orthogonal Multiple Access (NOMA) based MIMO system model for 6 G wireless communications was proposed, targeting the rate improvement of cell-edge users. The authors of [17] analyzed the asymptotic performance of multi-user MIMO communications with different linear receivers. However, although numerous techniques for combating signal attenuation are available for massive MIMO, this technology is challenges in mobility scenarios and is accompanied by the antenna and Radio Frequency (RF) front-end scalability problem.

Fortunately, the technologies of metasurface-based antennas and Reconfigurable Intelligent Surfaces (RISs) provide feasible and engaging research directions towards realizing highly flexible antennas at low cost [12], [18]–[24]. Specifically, an RIS is usually comprised of a large number of hardware-efficient and nearly passive reflecting elements, each of which can alter the phase of the incoming signal, without requiring a dedicated power amplifier [25]–[28]. Thus, the deployment of RISs enables the manipulation of electromagnetic (EM) waves, and brings benefit in low-power, energy-efficient, high-speed, massive-connectivity, and low-latency wireless communications [24], [29]–[34]. Due to its advantages, the research on RIS-assisted communications has gained remarkable research interest [35]–[39]. In [40], novel passive beamforming and information transfer technologies to enhance primary communication were proposed. Furthermore, NOMA in RIS-assisted communications was studied in [41] as a cost-effective solution for boosting spectrum/energy efficiency.

Inspired by the potential of RISs in 6 G wireless communications [42], the Holographic MIMO Surface (HMIMOS) concept aims at going beyond massive MIMO systems [43]–[46]. Specifically, an HMIMOS system incorporates densely packed sub-wavelength patch antennas to achieve programmable wireless environments [12], and it is verified to boost competitiveness in many fields, including NOMA, unmanned aerial vehicles, mmWaves, and multi-antenna systems [47]. The work in [48], [49] provided a comprehensive explanation of HMIMOS communications in wavenumber domain with plane waves. The work [43] proved theoretically the flexibility of HMIMOS configuration and its advantages in improving SE through intelligent environment configuration. The authors in [50] investigated the mutual coupling matrix [51], [52] in large RIS-assisted single-user communication systems, and showed that large RISs can achieve super-directivity. Benefiting from these merits, HMIMOS can be considered for many applications, including the extension of coverage, wireless power transfer, and indoor positioning [43]. However, the full exploitation of HMIMOS is still challenging due to many non-trivial technical issues.

One of the main challenges of the HMIMOS technology is multi-user channel modeling, due to the spatially continuous aperture realized by holographic patch antennas [5]. The

traditional channel models are not applicable for various reasons, e.g., the coupling between antennas, their massive numbers, and the surface-to-surface transmission. Thus, the shift towards infinite antennas and operating frequencies (i.e., mmWave and THz) requires an efficient EM model, since traditional independent Rayleigh fading models, which are based on the assumption of far-field EM wave propagation, might not be applicable [45], [46], [53]. Typically, in traditional channel models, the correlation between antennas is assumed to be zero with spacing larger than or equal to $\lambda/2$, however, when the spacing is less than $\lambda/2$, this will have the strong coupling effect in practice. Under such conditions, the spatial correlation [48], [54]–[56] among densely packed antennas cannot be ignored, and a tractable stochastic modeling tool is required to characterize the channel. In [1], beam pattern and channel estimation schemes for holographic RIS-assisted THz massive MIMO systems were presented, however, the channel was modeled in the beam domain, considering only the line-of-sight path. In [48], a spatially correlated small-scale fading model for single-user HMIMOS communication systems was proposed, employing samples of the random EM field to represent the EM channel. The research in [57]–[59] investigated the number of channel spatial Degrees of Freedom (DoF) in isotropic scattering environments, considering spatially-constrained apertures, and it was proved that the spatial DoF are proportional to the surface area, which is distinct from traditional analysis methods. When considering Multi-User HMIMOS (MU-HMIMOS) communication systems, another challenge is that simple linear precoding schemes, such as Zero-Forcing (ZF), with continuous-apertures surfaces are impractical due to the large amount of patch antennas.

Motivated by the EM-compliant channel model of [46], [48], [54] for single-user HMIMOS communication systems, this paper introduces a convenient channel model for MU-HMIMOS systems, and theoretically analyzes the SE performance of different linear precoding, which are designed exploiting features of the proposed model. Typically, the wireless channel empowered by an HMIMOS with infinite numbers of patch antennas is assumed to be on the continuous EM space in the optimal setting. To facilitate practical HMIMOS-based system designs, the continuous EM channel is sampled according to a specific placement and orientation of the patch antennas. Hence, the actual communication can be considered as a functional analysis problem depending only on geometric relationships, and the involved channel can be constructed as a combination of complete basis function sets of transmitter/receiver surfaces. In this manner, the ultimate performance metric for communications, namely the intrinsic capacity of the sampled space wireless channel, can be studied. Specifically, due to the fact that the EM channel can be characterized by complete basis functions, the SE can be theoretically analyzed using the variances of the sampled transmitter/receiver surfaces. In addition, the MU-HMIMOS concept involves massive patch antennas, thus, even simple linear precoding schemes (e.g., ZF and Minimum Mean-Square Error (MMSE)) are computationally heavy and costly, due to the expensive matrix inversion operation [60]–[65]. To solve this problem, we present a novel low-hardware-complexity ZF precoding scheme that is based on a Neumann Series (NS)

expansion, which replaces the expensive matrix inversion operation while being similar in terms of achievable sum rate with conventional ZF. The main contributions of this paper are summarized as follows:

- Building on the Fourier plane wave theory developed in [48], we extend the work to MU-HMIMOS communication systems. Specifically, the finite number of sampling points that carry channel information are collected to represent the spatially continuous channel, and the sampling is dependent on the spacing and the total amount of the surface's patch antennas.
- We investigate the SE of Maximum Ratio Transmission (MRT) and ZF precoding schemes in MU-HMIMOS communications, and derive the corresponding achievable rate capitalizing on the characteristics of the proposed EM-compliant channel model.
- We introduce a hardware-efficient ZF precoding scheme, leveraging NS expansion to replace the matrix inversion, as it is practically impossible to implement this operation due to the extremely large number of patch antennas in the envisioned MU-HMIMOS communication systems.
- We prove the validity of our theoretical capacity through simulation results and investigate the impact of spacing among the HMIMOS patch antennas, providing various insights on the surface's design.

The remainder of this paper is organized as follows. In Section II, the extended EM channel modeling for MU-HMIMOS communication systems is presented. Section III presents the analytical formulas for the SE with the considered precoding schemes and a low complexity NS-based ZF precoding scheme. Our simulation results are given in Section IV, while the concluded remarks of the paper are drawn in Section V.

Notation: Fonts a , \mathbf{a} , and \mathbf{A} represent scalars, vectors, and matrices, respectively. \mathbf{A}^T , \mathbf{A}^H , \mathbf{A}^{-1} , \mathbf{A}^\dagger , and $\|\mathbf{A}\|_F$ denote transpose, Hermitian (conjugate transpose), inverse, pseudo-inverse, and Frobenius norm of \mathbf{A} , respectively. $\mathbf{A}_{i,j}$ or $[\mathbf{A}]_{i,j}$ represents \mathbf{A} 's (i,j) -th element, while $[\mathbf{A}]_{i,:}$ and $[\mathbf{A}]_{:,j}$ stand for its i -th row and j -th column, respectively. $|\cdot|$ and $(\cdot)^*$ denote the modulus and conjugate, respectively. $\text{tr}(\cdot)$ gives the trace of a matrix, \mathbf{I}_n (with $n \geq 2$) is the $n \times n$ identity matrix, and $\mathbf{1}_n$ is a column vector with all ones. $\delta_{k,i}$ equals to 1 when $k = i$ or 0 when $k \neq i$, and \mathbf{e}_n is the n -th element unit coordinate vector with 1 in the n -th basis and 0's in each n' -th basis $\forall n' \neq n$. Finally, notation $\text{diag}(\mathbf{a})$ represents a diagonal matrix with the entries of \mathbf{a} on its main diagonal, $\delta(\cdot)$ is the Dirac delta function, and \odot is the Hadamard product. Table I includes a list with the most frequently-used parameters and variables throughout the paper.

II. EM-COMPLIANT CHANNEL MODELING

In this section, we capitalize on the approximated Fourier plane-wave series expansion, for the case of far-field EM wave propagation, and present an EM-compliant far-field channel model for multi-user HMIMOS communication systems.

TABLE I
PARAMETERS AND VARIABLES USED IN THIS PAPER

| Parameters/variables | Definitions |
|--|--|
| N_s, N_r | Number of patch antennas at the BS and each user, respectively. |
| $L_{s,x}, L_{s,y}$ | Horizontal and vertical length of the transmit surface. |
| $L_{r,x}, L_{r,y}$ | Horizontal and vertical length of the receive surface. |
| n_s, n_r | Number of sampling points at transmit surface and receive surface, respectively. |
| $\mathbf{k}, \mathbf{k}, k$ | Transmit wave vector, receive wave vector, and wavenumber, respectively. |
| \mathbf{H}, \mathbf{H}_a | Channel and the equivalent wave-domain channel, respectively. |
| $\mathbf{a}_s(\mathbf{k}, \mathbf{s}), \mathbf{a}_r(\mathbf{k}, \mathbf{r})$ | Source and receive responses in wave domain, respectively. |
| $A(k_x, k_y, \kappa_x, \kappa_y), S(k_x, k_y, \kappa_x, \kappa_y)$ | Spectral factor and spectral density at the point $(k_x, k_y, \kappa_x, \kappa_y)$ in the wave domain, respectively. |
| $\sigma^2(\ell_x, \ell_y, m_x, m_y)$ | Wave-domain channel variance of the sampling point $(\ell_x, \ell_y, m_x, m_y)$. |
| Φ, \mathbf{V} | Phase and precoding matrices, respectively. |
| $\tilde{\mathcal{R}}_{(\text{MRT})}, \tilde{\mathcal{R}}_{(\text{ZF})}$ | Theoretical capacity bound of the MRT and ZF precoding systems, respectively. |

Fig. 1. The considered MU-HMIMOS communication system consisting of an N_s patch antennas at BS end and M users with each having N_r patch antennas.

A. System Model

Consider the downlink communication between a BS and a group of M users that are both equipped with HMIMOS, as shown in Fig. 1. The HMIMOS at BS side is comprised of $N_s = N_V N_H$ unit cells, each made from metamaterials that are capable of adjusting their reflection coefficients, and the patch antennas spacing Δ_s is below half of the wavelength λ . The horizontal and vertical length of HMIMOS is $L_{s,x} = N_H \Delta_s$ and $L_{s,y} = N_V \Delta_s$. The HMIMOS patch antennas at BS are indexed row-by-row by $n \in [1, N_s]$, thus the location of the n -th patch antenna with respect to the origin is

$$\mathbf{s}_n = [s_x, s_y, s_z] = [0, i(n)\Delta_s, j(n)\Delta_s]^T, \quad (1)$$

where $i(n) = \text{mod}(n-1, N_H)$ and $j(n) = \lfloor (n-1)/N_H \rfloor$ are the horizontal and vertical indices of element n , respectively. Notice that $\text{mod}(\cdot, \cdot)$ denotes the modulus operation and $\lfloor \cdot \rfloor$ is the truncation of argument.

The transmit vector at HMIMOS with the azimuth angle φ and elevation angle θ is

$$\begin{aligned} \mathbf{a}_s(\boldsymbol{\kappa}, \mathbf{s}) &= [a_{s,1}(\boldsymbol{\kappa}, \mathbf{s}), \dots, a_{s,N_s}(\boldsymbol{\kappa}, \mathbf{s})] \\ &= \left[e^{j\boldsymbol{\kappa}(\varphi, \theta)^T \mathbf{s}_1}, \dots, e^{j\boldsymbol{\kappa}(\varphi, \theta)^T \mathbf{s}_{N_s}} \right]^T, \end{aligned} \quad (2)$$

where $\boldsymbol{\kappa}(\varphi, \theta) \in \mathbb{R}^3$ is the transmit wave vector

$$\begin{aligned} \boldsymbol{\kappa}(\varphi, \theta) &= [\kappa_x, \kappa_y, \kappa_z] \\ &= k[\cos(\theta) \cos(\varphi), \cos(\theta) \sin(\varphi), \sin(\theta)]^T, \end{aligned} \quad (3)$$

with $k = \frac{2\pi}{\lambda}$ being wavenumber.

Similarly, each user is equipped with N_r patch antennas with the spacing Δ_r . $L_{r,x}$ and $L_{r,y}$ denote the horizontal and vertical length, respectively. We assume that there are M users, and the location of m -th user is denoted by $\mathbf{r}_m = [r_{m,x}, r_{m,y}, r_{m,z}]$, $m = 1, \dots, M$. The receive vector is $\mathbf{a}_r(\mathbf{k}, \mathbf{r}) = [a_{r,1}(\mathbf{k}, \mathbf{r}), \dots, a_{r,M}(\mathbf{k}, \mathbf{r})]^T \in \mathbb{C}^{M \times 1}$, with

$$\mathbf{a}_{r,m}(\mathbf{k}, \mathbf{r}) = \left[e^{j\mathbf{k}^T \mathbf{r}_1^{(m)}}, \dots, e^{j\mathbf{k}^T \mathbf{r}_{N_r}^{(m)}} \right]^T, m = 1, \dots, M, \quad (4)$$

where $\mathbf{k} \in \mathbb{R}^3$ is the receive wave vector $\boldsymbol{\kappa} = [k_x, k_y, k_z]$.

B. Channel Modeling for Individual Users

Similar to Fourier transformation between time domain and frequency domain, there also exists transformation between the space domain and wavenumber domain. Specifically, the (m, n) -entry of the spatial domain channel $\mathbf{H} \in \mathbb{C}^{N_r \times N_s}$ can be obtained by the wavenumber domain channel $\mathbf{H}_a(k_x, k_y, \kappa_x, \kappa_y)$ [54, 4], i.e.,

$$\begin{aligned} [\mathbf{H}]_{mn} &= \frac{1}{(2\pi)^2} \iiint_{\mathcal{D}} a_{r,m}(\mathbf{k}, \mathbf{r}) H_a(k_x, k_y, \kappa_x, \kappa_y) \\ &\quad a_{s,n}(\boldsymbol{\kappa}, \mathbf{s}) dk_x dk_y d\kappa_x d\kappa_y, \end{aligned} \quad (5)$$

where $a_{s,n}(\boldsymbol{\kappa}, \mathbf{s})$ is the n -th element in (2), $a_{r,m}(\mathbf{k}, \mathbf{r})$ is the m -th element in (4), and integration region is $\mathcal{D} = \{(k_x, k_y) \in \mathbb{R}^2 : k_x^2 + k_y^2 \leq \kappa^2\}$ since the wave propagates along z -direction, and projection lies in X-Y plane.

The equivalent wavenumber domain channel is [54, 9]

$$\begin{aligned} H_a(k_x, k_y, \kappa_x, \kappa_y) &= S^{1/2}(k_x, k_y, \kappa_x, \kappa_y) W(k_x, k_y, \kappa_x, \kappa_y) \\ &= \frac{\kappa \eta}{2} \frac{A(k_x, k_y, \kappa_x, \kappa_y) W(k_x, k_y, \kappa_x, \kappa_y)}{k_z^{1/2}(k_x, k_y) \kappa_z^{1/2}(\kappa_x, \kappa_y)}, \end{aligned} \quad (6)$$

where the spectral density is $S(k_x, k_y, \kappa_x, \kappa_y) = \frac{A^2(k_x, k_y, \kappa_x, \kappa_y)}{k_z(k_x, k_y) \kappa_z(\kappa_x, \kappa_y)}$, and the spectral factor $A(k_x, k_y, \kappa_x, \kappa_y)$ is an arbitrary real-valued, non-negative function that is dependent on scattering environment [54, Theorem 1]. In isotropic scattering environment, $A(k_x, k_y, k_z) = \frac{2\pi}{\sqrt{k}}$ with unit channel power [48]. $W(k_x, k_y, \kappa_x, \kappa_y) \sim \mathcal{CN}(0, 1)$ is included to represent random characteristics.

In fact, $H_a(k_x, k_y, \kappa_x, \kappa_y)$ is the intermediate matrix between the transmit vector and receive vector in angular domain, which depends on the scattering environment and array geometry. Moreover, the more eigenvalues $H_a(k_x, k_y, \kappa_x, \kappa_y)$ has, the more strongly connected channels exist.

In wavenumber domain, the equivalent angular channel is a sparse and there are only finite non-zero elements, thus, the (5) can be approximated with finite sampling points in the effective bandwidth, i.e., the Fourier plane wave series expansion is non-zero only within the lattice ellipse [54]

$$\begin{aligned} \mathcal{E}_s &= \{(m_x, m_y) \in \mathbb{Z}^2 : (m_x \lambda / L_{s,x})^2 + (m_y \lambda / L_{s,y})^2 \leq 1\}, \\ \mathcal{E}_r &= \{(\ell_x, \ell_y) \in \mathbb{Z}^2 : (\ell_x \lambda / L_{r,x})^2 + (\ell_y \lambda / L_{r,y})^2 \leq 1\}, \end{aligned} \quad (7)$$

at the source and receiver, respectively. The cardinalities of the sets \mathcal{E}_s and \mathcal{E}_r are $n_s = |\mathcal{E}_s|$ and $n_r = |\mathcal{E}_r|$, respectively. To fully exploiting the channel information, the numbers of patch antennas at BS and each user are $N_s \geq n_s$ and $N_r \geq n_r$, respectively [54], [66].

Combining wavenumber domain channel at n_s and n_r sampling points in transmit and receive surface to approximate spatial channel \mathbf{H} , we have [54, Theorem 2]

$$\begin{aligned} [\mathbf{H}]_{mn} &\approx \sum_{(\ell_x, \ell_y) \in \mathcal{E}_r} \sum_{(m_x, m_y) \in \mathcal{E}_s} H_a(\ell_x, \ell_y, m_x, m_y) \\ &\quad a_{r,m}(\ell_x, \ell_y, \mathbf{r}) a_{s,n}(m_x, m_y, \mathbf{s}), \end{aligned} \quad (8)$$

where the Fourier coefficient is

$$H_a(\ell_x, \ell_y, m_x, m_y) \sim \mathcal{CN}(0, \sigma^2(\ell_x, \ell_y, m_x, m_y)), \quad (9)$$

with the variance $\sigma^2(\ell_x, \ell_y, m_x, m_y)$ is the variance of sampling point $(\ell_x, \ell_y, m_x, m_y)$, and it is separable under scattering separability, which can be computed from [48] as

$$\begin{aligned} \sigma^2(\ell_x, \ell_y, m_x, m_y) &\propto \iiint_{\hat{\mathcal{S}}_s \times \hat{\mathcal{S}}_r} \mathbb{1}_{\hat{\mathcal{D}}}(k_x, k_y) \mathbb{1}_{\hat{\mathcal{D}}}(\kappa_x, \kappa_y) \\ &\quad \frac{A^2(\hat{k}_x, \hat{k}_y, \hat{\kappa}_x, \hat{\kappa}_y)}{\hat{k}_z(\hat{k}_x, \hat{k}_y) \hat{\kappa}_z(\hat{\kappa}_x, \hat{\kappa}_y)} d\hat{k}_x d\hat{k}_y d\hat{\kappa}_x d\hat{\kappa}_y \\ &= \sum_{i=1}^3 \sum_{j=1}^3 \iiint_{\Omega_{s,j}(m_x, m_y) \times \Omega_{r,i}(\ell_x, \ell_y)} A^2(\theta_r, \phi_r, \theta_s, \phi_s) d\Omega_r d\Omega_s, \end{aligned} \quad (10)$$

where $(\hat{k}_x, \hat{k}_y, \hat{k}_z) = (k_x, k_y, k_z)/k$ are normalized wavevector coordinates, and integration region in receive wavenumber domain $\Omega_r(\ell_x, \ell_y)$ is divided into three subregions as shown in Fig. 2, $\Omega_s(m_x, m_y)$ is divided in the same way. For details refer to [48, Appendix IV.C]

Collecting all variances in $\boldsymbol{\Sigma}^{(m)} = (\boldsymbol{\sigma}_r^{(m)} \mathbf{1}_{n_s}^T) \odot (\mathbf{1}_{n_r} \boldsymbol{\sigma}_s^T)$, where $\boldsymbol{\sigma}_r^{(m)} \in \mathbb{R}^{n_r \times 1}$ and $\boldsymbol{\sigma}_s \in \mathbb{R}^{n_s \times 1}$ collect $\{\sqrt{N_r} \sigma_r^{(m)}(\ell_x, \ell_y)\}$ and $\{\sqrt{N_s} \sigma_s(m_x, m_y)\}$, respectively [54, Corollary 2]. $\sigma_{r,k}^{(m)}$ is the k -th element of $\boldsymbol{\sigma}_r^{(m)}$, and $\sigma_{s,i}$ is the i -th element of $\boldsymbol{\sigma}_s$, these variances are applied to capacity analysis in the next section.

Fig. 2. Integration regions $\Omega_r(\ell_x, \ell_y)$ of the variances $\sigma^2(\ell_x, \ell_y, m_x, m_y)$ in four orthants ($L_{r,x} \leq L_{r,y}$).

C. Channel Modeling for Multiple Users

This part extends the individual user channel modeling from the previous subsection to the multi-user case, we assume that different users are independently distributed in space, thus, the multi-user involved channel matrix can be decomposed into multiple channel matrices that corresponds to different users. For simplicity, the isotropic scattering environment is considered. To fully characterize EM channel, the HMIMOS patch antennas $N_s \geq \frac{4}{\lambda^2} L_{s,x} L_{s,y} \geq n_s$ at the BS end, and each user is equipped with $N_r \geq \frac{4}{\lambda^2} L_{r,x} L_{r,y} \geq n_r$ patch antennas, where Δ_s and Δ_r are patch antennas spacing at BS and user end. The channel of m -th user in matrix form $\mathbf{H}^{(m)} \in \mathbb{C}^{N_r \times N_s}$ is [54]

$$\mathbf{H}^{(m)} = \sqrt{N_r N_s} \sum_{(\ell_x, \ell_y) \in \mathcal{E}_r} \sum_{(m_x, m_y) \in \mathcal{E}_s} H_a^{(m)}(\ell_x, \ell_y, m_x, m_y) \mathbf{a}_r(\ell_x, \ell_y, \mathbf{r}^{(m)}) \mathbf{a}_s^H(m_x, m_y, \mathbf{s}), \quad (11)$$

where the Fourier coefficient

$$H_a^{(m)}(\ell_x, \ell_y, m_x, m_y) \sim \mathcal{N}_{\mathbb{C}}\left(0, \sigma_{(m)}^2(\ell_x, \ell_y, m_x, m_y)\right), \quad (12)$$

and [54]

$$\begin{aligned} [a_s(m_x, m_y, \mathbf{s})]_j &= \frac{1}{\sqrt{N_s}} e^{-j\left(\frac{2\pi}{L_{s,x}} m_x s_{x,j} + \frac{2\pi}{L_{s,y}} m_y s_{y,j} + \gamma_s(m_x, m_y) s_{z,j}\right)}, \\ j &= 1, \dots, N_s, \\ [a_r(\ell_x, \ell_y, \mathbf{r}^{(m)})]_i &= \frac{1}{\sqrt{N_r}} e^{-j\left(\frac{2\pi}{L_{r,x}} \ell_x r_{x,i}^{(m)} + \frac{2\pi}{L_{r,y}} \ell_y r_{y,i}^{(m)} + \gamma_r(\ell_x, \ell_y) r_{z,i}^{(m)}\right)}, \\ i &= 1, \dots, N_r. \end{aligned} \quad (13)$$

Denote $\mathbf{U}_s \in \mathbb{C}^{N_s \times n_s}$ as the matrix collecting the all variances of n_s sampling points in $a_s(m_x, m_y, \mathbf{s})$, and $\mathbf{U}_r^{(m)} \in \mathbb{C}^{N_r \times n_r}$ as the matrix collecting the all variances of n_r sampling points in $a_r(\ell_x, \ell_y, \mathbf{r}^{(m)})$. Specifically, $\mathbf{U}_s \mathbf{U}_s^H = \mathbf{I}_{n_s}$ and

$\mathbf{U}_r^{(m)} \mathbf{U}_r^{(m)H} = \mathbf{I}_{n_r}$ since their columns describe discretized transmit and receive plane-wave harmonics [54, 46].

Based on the above observation, the channel matrix can be approximated by spatial sampling n_s and n_r points at $j = 1, \dots, N_s$ -th patch antenna and the $i = 1, \dots, N_r$ -th received antenna for m -th user. Thus, [54]

$$\mathbf{H}^{(m)} = \mathbf{U}_r^{(m)} \mathbf{H}_a^{(m)} \mathbf{U}_s^H = \mathbf{U}_r^{(m)} \left(\Sigma^{(m)} \odot \mathbf{W} \right) \mathbf{U}_s^H, \quad (14)$$

where $\mathbf{H}_a^{(m)} = \Sigma^{(m)} \odot \mathbf{W} \in \mathbb{C}^{n_r \times n_s}$ collects $\sqrt{N_r N_s} H_a^{(m)}(\ell_x, \ell_y, m_x, m_y)$ for all $n_r n_s$ sampling points, and $\mathbf{W} \sim \mathcal{CN}(0, \mathbf{I}_{n_r n_s})$.

Thus, the correlation matrix of one user takes the form [54]

$$\begin{aligned} \mathbf{R}_H^{(m)} &= \mathbb{E} \left\{ \text{vec}(\mathbf{H}^{(m)}) \text{vec}(\mathbf{H}^{(m)})^H \right\} = \left(\mathbf{U}_s^* \otimes \mathbf{U}_r^{(m)} \right) \\ &\mathbb{E} \left\{ \left(\text{vec}(\Sigma^{(m)}) \odot \text{vec}(\mathbf{W}) \right) \left(\text{vec}(\mathbf{W}) \odot (\Sigma^{(m)})^H \right) \right\} \\ &\left(\mathbf{U}_s^T \otimes \mathbf{U}_r^{(m)H} \right). \end{aligned} \quad (15)$$

The channel $\mathbf{H} \in \mathbb{C}^{N_r M \times N_s}$ is given by

$$\begin{aligned} \mathbf{H} &= \left[\mathbf{U}_s^* \mathbf{H}_a^{(1)T} \mathbf{U}_r^{(1)T}, \dots, \mathbf{U}_s^* \mathbf{H}_a^{(M)T} \mathbf{U}_r^{(M)T} \right]^T \\ &= \mathbf{U}_r \mathbf{H}_a \mathbf{U}_s^H, \end{aligned} \quad (16)$$

where \mathbf{U}_r incorporates all received responses for M users, \mathbf{U}_s incorporates all transmit responses for all users, and $\mathbf{H}_a = [\mathbf{H}_a^{(1)T}, \dots, \mathbf{H}_a^{(M)T}]^T$ contains all equivalent channels in wavenumber domain for all users.

The correlation matrix is

$$\begin{aligned} \mathbf{R}_H &= \mathbb{E} \{ \text{vec}(\mathbf{H}) \text{vec}(\mathbf{H})^H \} \\ &= \begin{bmatrix} \mathbf{R}_{H^{(1)}} & 0 & \dots & 0 \\ 0 & \mathbf{R}_{H^{(2)}} & \dots & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & \dots & \mathbf{R}_{H^{(M)}} \end{bmatrix}. \end{aligned} \quad (17)$$

It can be observed from the above equations that the complex spatially correlated channel matrix $\mathbf{H}^{(m)} \in \mathbb{C}^{N_r \times N_s}$ is equivalent to a low-dimensional channel matrix $\mathbf{H}_a^{(m)} \in \mathbb{C}^{n_r \times n_s}$ since $N_s \geq n_s$ and $N_r \geq n_r$.

III. ACHIEVABLE RATE WITH LINEAR PRECODING

In this section, we derive the SE of the downlink MU-HMIMOS communication system adopting linear detectors (MRT and ZF). The perfect CSI is obtained at the receiver, and the phase matrix is assumed to be perfectly configured. Different from the conventional precoding analysis of MIMO system, the MU-HMIMOS system is equipped with a large number of patch antennas at both transmitter and receiver, which requires excessively high operational cost in practice, especially in the matrix inversion operation. In addition, in traditional MIMO system, each element in channel matrix is normally assumed to have the same unit variance, however, each entry in the constructed EM channel has different variances. Thus, the traditional analysis

methods in large MIMO system cannot be directly applied in the considered scenario. Based upon the equivalent wavenumber domain channel, we present a novel capacity evaluation method that requires the less computational cost and a hardware efficient NS-based ZF precoding scheme.

A. Ergodic Rate

The HMIMOS at the transmitter is composed of N_s patch antennas, and each user is equipped with N_r patch antennas. There are total M users, thus, the downlink MU-HMIMOS wireless communication system model is

$$\mathbf{y} = \sqrt{p_u} \mathbf{H} \Phi \mathbf{V} \mathbf{x} + \mathbf{w} = \sqrt{p_u} \mathbf{U}_r \mathbf{H}_a \mathbf{U}_s^H \Phi \mathbf{V} \mathbf{x} + \mathbf{w}, \quad (18)$$

where $\mathbf{y} \in \mathbb{C}^{N_r M \times 1}$ is the received signal; $\mathbf{H} \in \mathbb{C}^{N_r M \times N_s}$ is the channel matrix; $\Phi = \text{diag}(\phi) \in \mathbb{C}^{N_s \times N_s}$, $\phi = [e^{j\phi_1}, \dots, e^{j\phi_{N_s}}]^T \in \mathbb{C}^{N_s \times 1}$ is the phase vector of HMIMOS part composed of N_s patch antennas. p_u is the transmitted power; $\mathbf{V} \in \mathbb{C}^{N_s \times N_r M}$ is the precoding matrix; $\mathbf{x} \in \mathbb{C}^{N_r M \times 1}$ is the transmitted signal, and $\mathbf{w} \in \mathbb{C}^{N_r M \times 1}$ is additive Gaussian noise that has i.i.d. elements with zero mean and variance σ_w^2 .

Let $\mathbf{y}_a = \mathbf{U}_r^H \mathbf{y} \in \mathbb{C}^{N_r M \times 1}$ the received signal in wavenumber domain, $\tilde{\mathbf{H}}_a = \mathbf{H}_a \mathbf{U}_s^H \Phi \in \mathbb{C}^{N_r M \times N_s}$ is the equivalent channel that incorporates the phase matrix. Thus,

$$\mathbf{y}_a = \sqrt{p_u} \tilde{\mathbf{H}}_a \mathbf{V} \mathbf{x} + \mathbf{w}. \quad (19)$$

The final signal received by m -th user at i -th received sampling point can be given by

$$[y_a^{(m)}]_i = [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} [\mathbf{V}^{(m)}]_{:,i} x_i^{(m)} + [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} [\mathbf{V}^{(m)}]_{:,i'} x_{i'}^{(m)} + w_i^{(m)}, \quad (20)$$

where $\mathbf{x}^{(m)} = [x_1^{(m)}, \dots, x_{N_r}^{(m)}] \in \mathbb{C}^{N_r \times 1}$ is the transmitted signal of m -th user, with $x_i^{(m)}$ the i -th entry. $\mathbf{V}^{(m)} \in \mathbb{C}^{N_s \times N_r}$ is the m -th sub-block in precoding matrix corresponding to the m -th user, and $[\mathbf{V}^{(m)}]_{:,i}$ is the i -th column. $\tilde{\mathbf{H}}_a^{(m)}$ is the m -th sub-block of the channel channel matrix $\tilde{\mathbf{H}}_a$, and $[\tilde{\mathbf{H}}_a^{(m)}]_{i,:}$ is the i -th row. $\mathbf{y}^{(m)} \in \mathbb{C}^{N_r \times 1}$ is the received signal of m -th user, and $[y_a^{(m)}]_i$ is the i -th element. Therefore, the achievable rate of the m -th user at i -th received response point $i = 1, \dots, n_r$ can be given by

$$\mathcal{R}^{(m),i} = \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u \left| [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} [\mathbf{V}^{(m)}]_{:,i} \right|^2}{p_u \left| [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} [\mathbf{V}^{(m)}]_{:,i'} \right|^2 + \sigma_w^2} \right) \right\}. \quad (21)$$

B. MRT Precoding

In MRT precoding, $\mathbf{V} = \alpha_{\text{MRT}} \tilde{\mathbf{H}}_a^H$, where α_{MRT} is the normalization coefficient to satisfy the power constraint $\mathbb{E}\{\text{Tr}(\mathbf{V}\mathbf{V}^H)\} = 1$, we have

$$\begin{aligned} \alpha_{\text{MRT}} &= \sqrt{\frac{1}{\mathbb{E}\{\text{Tr}(\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)\}}} = \sqrt{\frac{1}{\mathbb{E}\{\text{Tr}(\mathbf{H}_a \mathbf{H}_a^H)\}}} \\ &= \sqrt{\frac{1}{\sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \sigma_{r,i}^2 \sigma_{s,j}^2}}. \end{aligned} \quad (22)$$

This is equivalent to normalize each column of precoding matrix \mathbf{V} , i.e., $\mathbf{V}_{:,i} = \frac{\tilde{\mathbf{g}}_i}{\|\mathbf{V}\|_F}$, where $\tilde{\mathbf{g}}_i$ is the i -th row of equivalent channel $\tilde{\mathbf{H}}_a$, i.e., $\tilde{\mathbf{H}}_a^H = [\tilde{\mathbf{g}}_1, \dots, \tilde{\mathbf{g}}_{n_r}]$, and $\alpha_{\text{MRT}} = \frac{1}{\|\mathbf{V}\|_F}$. Thus,

$$\begin{aligned} \mathcal{R}_{(\text{MRT})}^{(m),i} &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u \alpha_{\text{MRT}}^2 \left| [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} [\tilde{\mathbf{H}}_a^{(m)}]_{:,i}^H \right|^2}{p_u \alpha_{\text{MRT}}^2 \left| [\tilde{\mathbf{H}}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} [\tilde{\mathbf{H}}_a^{(m)}]_{:,i'}^H \right|^2 + \sigma_w^2} \right) \right\} \\ &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u \alpha_{\text{MRT}}^2 \left| [\mathbf{H}_a^{(m)}]_{i,i} [\mathbf{H}_a^{(m)}]_{i,i}^H \right|^2}{p_u \alpha_{\text{MRT}}^2 \left| [\mathbf{H}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} [\mathbf{H}_a^{(m)}]_{:,i'}^H \right|^2 + \sigma_w^2} \right) \right\} \\ &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u \alpha_{\text{MRT}}^2 \left| \mathbf{g}_i^H \mathbf{g}_i \right|^2}{p_u \alpha_{\text{MRT}}^2 \sum_{i' \neq i}^{n_r} \left| \mathbf{g}_i^H \mathbf{g}_{i'} \right|^2 + \sigma_w^2} \right) \right\}, \end{aligned} \quad (23)$$

where \mathbf{g}_i is the i -th column of matrix \mathbf{H}_a^H . The superscript (m) is omitted for the purpose of simplification in the following derivation. To further derive the bound of the MRT precoding system, we adopt Jensen's inequality, specifically,

$$\begin{aligned} \mathcal{R}_{(\text{MRT})}^{(m),i} &\geq \log_2 \left(1 + \left(\mathbb{E} \left\{ \frac{p_u \alpha_{\text{MRT}}^2 \sum_{i' \neq i}^{n_r} \left| \mathbf{g}_i^H \mathbf{g}_{i'} \right|^2 + \sigma_w^2}{p_u \alpha_{\text{MRT}}^2 \left| \mathbf{g}_i^H \mathbf{g}_i \right|^2} \right\} \right)^{-1} \right), \end{aligned} \quad (24)$$

where $\|[\mathbf{H}_a^{(m)}]_{i,:} \mathbf{g}_{i'}\|^2 = n_s \hat{\sigma}_s^2 \sigma_{r,i}^2$, $\|[\mathbf{H}_a^{(m)}]_{i,:} \mathbf{g}_i\|^2 = (n_s^2 + n_s) \hat{\sigma}_s^2 \sigma_{r,i}^2$, and $\|\mathbf{V}\|_F^2 = \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \sigma_{r,i}^2 \sigma_{s,j}^2 \approx n_s \hat{\sigma}_s^2 \sum_{i=1}^{n_r} \sigma_{r,i}^2$.

Due to

$$\begin{aligned} &\mathbb{E} \left\{ \frac{p_u \alpha_{\text{MRT}}^2 \sum_{i' \neq i}^{n_r} \left| \mathbf{g}_i^H \mathbf{g}_{i'} \right|^2 + \sigma_w^2}{p_u \alpha_{\text{MRT}}^2 \|\mathbf{g}_i\|^4} \right\} \\ &= \left(\sum_{i' \neq i}^{n_r} \mathbb{E} \left\{ \tilde{g}_{i'}^2 \right\} \right) \mathbb{E} \left\{ \frac{1}{\|\mathbf{g}_i\|^2} \right\} + \mathbb{E} \left\{ \frac{\sigma_w^2}{p_u \alpha_{\text{MRT}}^2 \left| \mathbf{g}_i^H \mathbf{g}_i \right|^2} \right\}, \end{aligned} \quad (25)$$

where $\tilde{g}_{i'} = \frac{\mathbf{g}_i^H \mathbf{g}_{i'}}{\|\mathbf{g}_i\|}$, and \mathbf{g}_i is variable with zero mean and variance $\beta_{i'} = \sigma_{r,i'}^2 \hat{\sigma}_s^2$, where $\hat{\sigma}_s^2 = \frac{1}{n_s} \sum_{j=1}^{n_s} \sigma_{s,j}^2$, which is used to approximate the lower bound in derivation.

$$\mathbb{E} \left\{ \frac{1}{\|\mathbf{g}_i\|^2} \right\} = \frac{1}{\sum_{j=1}^{n_s} \sigma_{r,i}^2 \sigma_{s,j}^2} = \frac{1}{(n_s - 1) \hat{\sigma}_s^2 \sigma_{r,i}^2}. \quad (26)$$

$$\mathbb{E} \left\{ \frac{1}{\left| \mathbf{g}_i^H \mathbf{g}_i \right|^2} \right\} = \frac{1}{(n_s - 1)(n_s - 2) \hat{\sigma}_s^4 \sigma_{r,i}^4}. \quad (27)$$

Substituting (26) and (27) into (25), we have

$$\begin{aligned} \mathbb{E} \left\{ \frac{p_u \alpha_{\text{MRT}}^2 \sum_{i' \neq i}^{n_r} |\mathbf{g}_i^H \mathbf{g}_{i'}|^2 + \sigma_w^2}{p_u \alpha_{\text{MRT}}^2 \|\mathbf{g}_i\|^4} \right\} \\ = \frac{\hat{\sigma}_s^2 \sum_{i' \neq i}^{n_r} \sigma_{r,i'}^2}{(n_s - 1) \hat{\sigma}_s^2 \sigma_{r,i}^2} + \frac{\sigma_w^2}{p_u \alpha_{\text{MRT}}^2 (n_s - 1)(n_s - 2) \hat{\sigma}_s^4 \sigma_{r,i}^4} \\ = \frac{p_u (n_s - 2) \hat{\sigma}_s^2 \sigma_{r,i}^2 \sum_{i' \neq i}^{n_r} \sigma_{r,i'}^2 + \sigma_w^2 n_s \sum_{i=1}^{n_r} \sigma_{r,i}^2}{p_u (n_s - 1)(n_s - 2) \hat{\sigma}_s^4 \sigma_{r,i}^4}, \quad (28) \end{aligned}$$

where $\alpha_{\text{MRT}} = \sqrt{\frac{1}{n_s \hat{\sigma}_s^2 \sum_{i=1}^{n_r} \sigma_{r,i}^2}}$. Thus, the theoretical capacity bound is given by

$$\begin{aligned} \tilde{\mathcal{R}}_{(\text{MRT})}^{(m),i} \\ \geq \log_2 \left(1 + \frac{p_u (n_s - 1)(n_s - 2) \hat{\sigma}_s^2 \sigma_{r,i}^4}{p_u (n_s - 2) \hat{\sigma}_s^2 \sigma_{r,i}^2 \sum_{i' \neq i}^{n_r} \sigma_{r,i'}^2 + \sigma_w^2 n_s \sum_{i=1}^{n_r} \sigma_{r,i}^2} \right) \\ \stackrel{n_s \gg 2}{\approx} \log_2 \left(1 + \frac{p_u n_s \hat{\sigma}_s^2 \sigma_{r,i}^4}{p_u \hat{\sigma}_s^2 \sigma_{r,i}^2 \sum_{i' \neq i}^{n_r} \sigma_{r,i'}^2 + \sigma_w^2 \sum_{i=1}^{n_r} \sigma_{r,i}^2} \right). \quad (29) \end{aligned}$$

C. ZF Precoding

This precoding scheme intends at eliminating interference among different users by setting the precoding matrix as $\mathbf{V} = \alpha_{\text{ZF}} \tilde{\mathbf{H}}_a^H (\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)^{-1}$, where α_{ZF} is the normalization factor to obey the constraint $\mathbb{E}\{\text{Tr}(\mathbf{V}\mathbf{V}^H)\} = 1$. In this case, it holds $\alpha_{\text{ZF}} \tilde{\mathbf{H}}_a^{(m)} \mathbf{V}^{(m)} = \mathbf{I}_{n_r}$. We adopt the vector normalization method in [67], i.e., $\tilde{\mathbf{H}}_a^H (\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)^{-1} = [\mathbf{f}_1, \dots, \mathbf{f}_{n_r}]$, $\mathbf{V}_{:,i} = \frac{\mathbf{f}_i}{\sqrt{n_r} \|\mathbf{f}_i\|}$. It should be noted that MRT and ZF adopt different normalization methods to reduce noise impact for better exploitation of performance. Specifically, from analytical numerical results in [67], MRT with matrix normalization is better than vector normalization, and ZF with vector normalization is better than that with matrix normalization in achievable rate bounds. Thus, the achievable rate is given by

$$\begin{aligned} \mathcal{R}_{(\text{ZF})}^{(m),i} &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u |[\tilde{\mathbf{H}}_a^{(m)}]_{i,:} [\mathbf{V}^{(m)}]_{:,i}^{-1}|^2}{p_u |[\tilde{\mathbf{H}}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} |[\tilde{\mathbf{H}}_a^{(m)}]_{:,i'}^{-1}|^2 + \sigma_w^2} \right) \right\} \\ &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u |[\mathbf{H}_a^{(m)}]_{i,:} [\mathbf{H}_a^{(m)}]_{:,i}^{-1}|^2}{p_u \alpha_{\text{ZF}}^2 |[\mathbf{H}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} |[\mathbf{H}_a^{(m)}]_{:,i'}^{-1}|^2 + \sigma_w^2} \right) \right\} \\ &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u |[\mathbf{H}_a^{(m)}]_{i,:} \frac{\mathbf{f}_i}{\sqrt{n_r} \|\mathbf{f}_i\|}|^2}{p_u |[\mathbf{H}_a^{(m)}]_{i,:} \sum_{i' \neq i}^{n_r} \frac{\mathbf{f}_{i'}}{\sqrt{n_r} \|\mathbf{f}_{i'}\|}|^2 + \sigma_w^2} \right) \right\} \\ &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u}{n_r \sigma_w^2 \|\mathbf{f}_i\|^2} \right) \right\}. \quad (30) \end{aligned}$$

We adopt the mathematical method in [68] to analyze the theoretical capacity. Due to $\mathbf{f}_i = \tilde{\mathbf{H}}_a^H (\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)^{-1} \mathbf{e}_i$, where \mathbf{e}_i is a column vector that is 1 at i -th entry and 0 otherwise, the term $\frac{1}{\|\mathbf{f}_i\|^2}$ can be given as

$$\begin{aligned} \beta_i &= \frac{1}{\|\mathbf{f}_i\|^2} = \frac{1}{\|\tilde{\mathbf{H}}_a^H (\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)^{-1} \mathbf{e}_i\|^2} \\ &= \frac{1}{\mathbf{e}_i^T (\tilde{\mathbf{H}}_a \tilde{\mathbf{H}}_a^H)^{-1} \mathbf{e}_i} = \frac{\det[\mathbf{H}_a \mathbf{H}_a^H]}{\det[\mathbf{H}_a^{(i)-} [\mathbf{H}_a^{(i)-}]^H]}, \quad (31) \end{aligned}$$

where $\mathbf{H}_a^{(i)-}$ is the matrix of \mathbf{H}_a deleting i -th row, and \det denotes the determinant of a matrix. We have [68]

$$\det[\mathbf{H}_a \mathbf{H}_a^H] = \sum_{i=1}^{n_r} (-1)^{i-1} \mathbf{g}_1^H \mathbf{g}_i \det[\mathbf{H}_a^{(1)-} [\mathbf{H}_a^{(i)-}]^H]. \quad (32)$$

Thus,

$$\begin{aligned} \beta_1 &= \mathbf{g}_1^H \mathbf{g}_1 - \frac{\sum_{i=2}^{n_r} (-1)^i \mathbf{g}_1^H \mathbf{g}_i \det[\mathbf{H}_a^{(1)-} [\mathbf{H}_a^{(i)-}]^H]}{\det[\mathbf{H}_a^{(1)-} [\mathbf{H}_a^{(1)-}]^H]} \\ &= \mathbf{g}_1^H \mathbf{g}_1 - \sum_{i=2}^{n_r} (-1)^i \mathbf{g}_1^H \mathbf{g}_i \frac{\sum_{k=2}^{n_r} (-1)^{k-1} \mathbf{g}_k^H \mathbf{g}_1 \det[\mathbf{M}_k]}{\sum_{j=2}^{n_r} (-1)^{j-1} \mathbf{g}_j^H \mathbf{g}_i \det[\mathbf{M}_j]} \\ &= \mathbf{g}_1^H \mathbf{g}_1 - \sum_{i=2}^{n_r} \frac{\sum_{k=2}^{n_r} (-1)^{k-1} \mathbf{g}_k^H \mathbf{g}_1 \mathbf{g}_1^H \mathbf{g}_i \det[\mathbf{M}_k]}{\sum_{j=2}^{n_r} (-1)^{j-1} \mathbf{g}_j^H \mathbf{g}_i \det[\mathbf{M}_j]}, \quad (33) \end{aligned}$$

where \mathbf{M}_k is the sub-block matrix of $\mathbf{H}_a^{(1)-} [\mathbf{H}_a^{(1)-}]^H$ with removal of the k -th row and the i -th column. Using the fact that each element in \mathbf{H}_a is independent, and $\mathbb{E}\{[\mathbf{H}_a]_{i,j}^2\} = \sigma_{r,i}^2 \sigma_{s,j}^2$ under separable scattering environment, we have $\mathbb{E}\{\mathbf{g}_1 \mathbf{g}_1^H\} = \text{diag}[\sigma_{r,1}^2 \sigma_{s,1}^2, \dots, \sigma_{r,1}^2 \sigma_{s,n_s}^2]$. Thus,

$$\begin{aligned} \mathbb{E} \left\{ \frac{\sum_{k=2}^{n_r} (-1)^{k-1} \mathbf{g}_k^H \mathbf{g}_1 \mathbf{g}_1^H \mathbf{g}_i \det[\mathbf{M}_k]}{\sum_{j=2}^{n_r} (-1)^{j-1} \mathbf{g}_j^H \mathbf{g}_i \det[\mathbf{M}_j]} \right\} \\ = \mathbb{E} \left\{ \frac{\sum_{k=2}^{n_r} (-1)^{k-1} \mathbf{g}_k^H \mathbb{E}\{\mathbf{g}_1 \mathbf{g}_1^H\} \mathbf{g}_i \det[\mathbf{M}_k]}{\sum_{j=2}^{n_r} (-1)^{j-1} \mathbf{g}_j^H \mathbf{g}_i \det[\mathbf{M}_j]} \right\} \\ \stackrel{(a)}{=} \sigma_{r,1}^2 \hat{\sigma}_s^2, \quad (34) \end{aligned}$$

where (a) simplifies the derivation using average variances, i.e., $\mathbb{E}\{\mathbf{g}_1 \mathbf{g}_1^H\} = \sigma_{r,1}^2 \hat{\sigma}_s^2 \mathbf{I}_{n_s}$. As a result,

$$\begin{aligned} \mathbb{E}\{\beta_1\} &= \mathbb{E} \left\{ \frac{1}{\|\mathbf{f}_1\|^2} \right\} = \mathbb{E}\{\mathbf{g}_1^H \mathbf{g}_1\} \\ &\quad - \mathbb{E} \left\{ \sum_{i=2}^{n_r} \frac{\sum_{k=2}^{n_r} (-1)^{k-1} \mathbf{g}_k^H \mathbf{g}_1 \mathbf{g}_1^H \mathbf{g}_i \det[\mathbf{M}_k]}{\sum_{j=2}^{n_r} (-1)^{j-1} \mathbf{g}_j^H \mathbf{g}_i \det[\mathbf{M}_j]} \right\} \\ &\approx \sigma_{r,1}^2 \sum_{j=1}^{n_s} \sigma_{s,j}^2 - (n_r - 1) \sigma_{r,1}^2 \hat{\sigma}_s^2 \\ &= (n_s - n_r + 1) \sigma_{r,1}^2 \hat{\sigma}_s^2. \quad (35) \end{aligned}$$

Based upon the above observation, we can derive the theoretical capacity as

$$\begin{aligned} \tilde{\mathcal{R}}_{(\text{ZF})}^{(m),i} &= \mathbb{E} \left\{ \log_2 \left(1 + \frac{p_u}{n_r \sigma_w^2 \|\mathbf{f}_i\|^2} \right) \right\} \\ &\approx \log_2 \left(1 + \frac{p_u}{n_r \sigma_w^2} (n_s - n_r + 1) \sigma_{r,i}^2 \hat{\sigma}_s^2 \right). \quad (36) \end{aligned}$$

D. NS-Based ZF Precoding

The ZF precoding scheme involves the inverse operation of the $n_r \times n_r$ matrix, a traditional approach is to compute the exact inverse of the matrix $\mathbf{Z} = \mathbf{H}_a \mathbf{H}_a^H$ in

$$\mathbf{V} = \alpha_{ZF} \mathbf{H}_a^{-1} = \mathbf{H}_a^H (\mathbf{H}_a \mathbf{H}_a^H)^{-1} = \mathbf{H}_a^H \mathbf{Z}^{-1}. \quad (37)$$

However, the large number of patch antennas in MU-HMIMOS communications imposes challenges to precoding design in practice. Specifically, the computation of matrix inversion would be excessively high as n_r grows large, and even for the simple linear ZF precoding that is still impractical. Thus, we employ NS expansion to replace the matrix inversion. Specifically, in separable scattering environment,

$$\begin{aligned} \mathbf{Z}^{-1} &= (\mathbf{H}_a \mathbf{H}_a^H)^{-1} \\ &= (\text{diag}(\boldsymbol{\sigma}_r) \mathbf{W} \text{diag}(\boldsymbol{\sigma}_s^2) \mathbf{W}^H \text{diag}(\boldsymbol{\sigma}_r))^{-1} \\ &= \text{diag}(\boldsymbol{\sigma}_r)^{-1} \tilde{\mathbf{W}}^{-1} \text{diag}(\boldsymbol{\sigma}_r)^{-1}, \end{aligned} \quad (38)$$

where $\tilde{\mathbf{W}} = \mathbf{W} \text{diag}(\boldsymbol{\sigma}_s^2) \mathbf{W}^H$, and $\boldsymbol{\sigma}_s^2$ is the element-wise square operation of $\boldsymbol{\sigma}_s$. $\text{diag}(\boldsymbol{\sigma}_s^2)$ and $\text{diag}(\boldsymbol{\sigma}_r)$ are diagonal matrix that are easily to compute the matrix inversion, thus the computational cost mainly lies in the computation of $\tilde{\mathbf{W}}^{-1}$. However, if Gram matrix $\tilde{\mathbf{W}}$ is not a strongly diagonally dominant or even not dominant at all, the Neumann method cannot be applied in the computation of $\tilde{\mathbf{W}}^{-1}$ directly, which may result in the slow convergence or even divergence [69]. Fortunately, in the special case of single ended correlation, (i.e., transmit correlation, or receive correlation, but not both are considered), the Neumann method works well as follows.

In Neumann method, the Gram matrix $\tilde{\mathbf{W}}$ is decomposed into its main diagonal matrix \mathbf{D} and off-diagonal matrix \mathbf{E} [69], i.e., $\tilde{\mathbf{W}} = \mathbf{D} + \mathbf{E}$. The inverse of $\tilde{\mathbf{W}}$ is given by

$$\tilde{\mathbf{W}}^{-1} = \sum_{i=0}^{\infty} (-\mathbf{D}^{-1} \mathbf{E})^i \mathbf{D}^{-1}. \quad (39)$$

The inverse of $\tilde{\mathbf{W}}$ is approximated by a summation of powers of a matrix (matrix multiplications), which has a complexity order $\mathcal{O}(in_r^3)$ (i is the iteration number). Although the complexity order can be equal or higher (depending on iteration number i) than computing the exact inverse, matrix multiplications are preferable in hardware compared to the exact inversion [64]. In addition, increasing the iteration number i brings a higher precision of the matrix inversion at a higher computational cost. In this paper, the iteration number i is set to be 4 for efficient computation at the low computational cost.

IV. NUMERICAL RESULTS

In this section, we present computer simulation results of the downlink SE in the considered MU-HMIMOS system as well as the theoretical capacity. The single-sided correlation [70] and three users are considered. All capacity curves were obtained after averaging over 800 independent Monte Carlo channel realizations.

Fig. 3. The eigenvalues of \mathbf{R} in decreasing order for MU-HMIMOS communication system with $N_s = 900$, $N_r = 576$, $\Delta_s = \lambda/3$ and $\Delta_r \in \{\lambda/6, \lambda/3, \lambda/2\}$.

Fig. 3 illustrates the eigenvalues of channel correlation matrix \mathbf{R}_H in decreasing order in a setup with $N_s = 900$, $N_r = 576$, $\Delta_s = \lambda/3$ for different spacing in received patch antennas. From the figure, eigenvalues are large but non-identical initially, and then the eigenvalues quickly approach zero. This means the strengths of the coupling coefficients are not all equal even in isotropic propagation, which shows that the MU-HMIMOS channel exhibits spatial correlation. In addition, the smaller spacing among patch antennas, the more uneven the coupling coefficients and the steeper the eigenvalues decay, which implies stronger correlation. Specifically, the curve with $\Delta_r = \lambda/2$ decays much slower than that with $\Delta_r = \lambda/6$. The i.i.d. Rayleigh is also showed in black dot curve as reference. Normally, the spacing $\lambda/2$ is regarded as a threshold to maintain zero correlation among antennas, however, this is only an ideal assumption. Actually, the $\lambda/2$ still shows correlation in practice, thus, there is a difference between the case $\lambda/2$ and i.i.d. case. We can see from the figure that none of the curves resembles the reference case, even the curve $\Delta_r = \lambda/2$ that is the closest one still has a major difference. These observations all prove that an EM channel in MU-HMIMOS systems should not adopt i.i.d. Rayleigh fading modeling.

Fig. 4 shows the SE of ZF precoding and theoretical ZF precoding schemes with $N_r = 144$, $\Delta_s = \Delta_r = \lambda/3$ for different number of transmit patch antennas, and MMSE precoding scheme is set as benchmark curve. As shown in figure, there is very small gap between the ZF precoding and theoretical ZF schemes. Specifically, at lower SNR, the theoretical ZF perfectly predicts the ZF precoding scheme. Thus, the effectiveness of the presented theoretical capacity is proved. Naturally, the more transmit patch antennas bring more benefits in SE. This can be accounted for that transmit surface is larger with the increase of patch antennas given the fixed spacing. What's more, the gap between ZF precoding and benchmark MMSE precoding is narrower with the increase of transmit patch antennas in high SNR region. This is mainly because the noise has little impact on ZF precoding when SNR goes high.

Fig. 4. SE of ZF precoding, theoretical ZF precoding and MMSE precoding schemes for different transmit patch antennas with $N_r = 144$, $\Delta_s = \Delta_r = \lambda/3$.

Fig. 5. SE of MRT precoding scheme for different transmit patch antennas with $N_r = 144$, $\Delta_s = \Delta_r = \lambda/3$.

The SE of MRT precoding and theoretical MRT precoding schemes with $N_r = 144$, $\Delta_s = \Delta_r = \lambda/3$ for different number of transmit patch antennas are given in Fig. 5. The similar conclusion drawn from Fig. 4 can also be obtained in Fig. 5, i.e., the theoretical MRT can predict MRT precoding scheme in all SNR regions. Shown in the figure, the curves for $N_s = 144$ reach plateau at SNR=10 dB, this is because MRT shows advantages when the noise is dominant. With the increase of transmit patch antennas, not only the SE increases, but the point to reach plateau also moves further, and this phenomenon can be accounted for the larger transmit surface generated by the increase of patch antennas.

The impact of received patch antennas on the SE of MRT, ZF and MMSE precoding schemes for $N_s = 900$, $\Delta_s = \Delta_r = \lambda/6$ is given in Fig. 6. As shown in figure, the MRT precoding is better than ZF precoding in the low SNR region, which is contrary to the case in the high SNR region. This is mainly due to the impact of noise, i.e., the noise is dominant in low SNR region, thus, MRT is better, while the noise impact is finite in the high SNR region,

Fig. 6. SE of MRT, ZF and MMSE precoding schemes for different received patch antennas with $N_s = 900$, $\Delta_s = \Delta_r = \lambda/6$.

Fig. 7. SE of ZF and MMSE precoding schemes for different spacing with $N_s = 3600$, $N_r = 144$, $\Delta_r = \lambda/3$.

thus, ZF is better. As a benchmark, MMSE performs the best in the whole SNR region, and the gap between ZF and MMSE gradually decreases with the increase of SNR. In addition, the more received patch antennas bring benefits in SE. As observed from figure, the case $N_r = 288$ achieves the best performance compared with $N_r = 72$ and $N_r = 144$. This can be accounted for the larger received surface area enlarged by more received patch antennas under the fixed spacing.

The impact of transmit spacing on SE for MMSE, ZF, theoretical ZF, MRT and theoretical MRT precoding schemes are given in Figs. 7 and 8, respectively, under the settings of $N_s = 3600$, $N_r = 144$, $\Delta_r = \lambda/3$. From the Fig. 7, smaller spacing with fixed number of patch antennas has less surface area and induces more correlation among patch antennas, thus, the SE is worse. Specifically, the ZF precoding scheme with $\Delta_s = \lambda/15$ has worse performance than $\Delta_s = \lambda/6$. In other words, there is a large reduction in correlated channel with larger spacing. Normally, the spacing $\Delta_s = \Delta_r = \lambda/2$ is adopted in the uncorrelated channel assumption for SE analysis [14]. In addition, the theoretical ZF with closer spacing predicts the

Fig. 8. SE of MRT precoding schemes for different spacing with $N_s = 3600$, $N_r = 144$, $\Delta_r = \lambda/3$.

Fig. 9. Comparison of ZF precoding scheme and NS-based ZF precoding for different iterations with $N_s = 729$, $N_r = 144$, $\Delta_s = \Delta_r = \lambda/3$.

ZF precoding well, thus, the presented theoretical ZF could perform well in highly correlated cases. The similar observation is also obtained in Fig. 8. Specifically, the theoretical MRT with $\Delta_s = \lambda/15$ predicts that the performance of MRT is better than the case $\Delta_s = \lambda/6$ in the whole SNR region. Both figures show that less spacing has a lower SE and the proposed theoretical analyses perform well in highly correlated cases.

Fig. 9 shows the impact of iteration on the SE for NS-based ZF precoding scheme with $N_s = 729$, $N_r = 144$ and $\Delta_s = \Delta_r = \lambda/3$. Shown in the figure, the ZF precoding employing NS with more iterations is closer to the ZF precoding scheme. Specifically, the case with 4-th iteration almost coincides that with 7-th iteration, and there is also just a narrow gap between 4-th iteration and 3-rd iteration. Thus, we normally adopt 4 iterations in practical simulations for achieving a balance between the computational cost and performance. The simulation result also proves the effectiveness of NS-based ZF precoding scheme since it achieves the similar performance with ZF while avoiding expensive matrix inversion operation.

V. CONCLUSION

In this paper, we extended an EM-compliant channel model to MU-HMIMOS communication systems. The presented spatial channel is modeled in the wavenumber domain using the Fourier plane wave approximation, and it accounts for the inevitable mutual coupling induced by the close patch antenna spacing. We also analytically investigated the MRT and ZF precoding schemes, deriving the theoretical expressions for the achievable SE performance. Furthermore, a hardware efficient NS-based ZF precoding scheme was proposed to replace the involved matrix inversion, which renders the application of conventional ZF precoders impractical. Our simulation results verified that the more patch antennas with fixed spacing are present at the HMIMOS transmitter and receiver, the larger is the achievable SE performance. However, when the spacing among the antennas decreases, stronger signal correlations are generated, the SE is degraded. It was also demonstrated that the proposed NS-based ZF precoding scheme can achieve similar performance to conventional ZF at a lower hardware cost.

Li Wei received the B.S. degree in communication engineering from Southwest Jiaotong University, Chengdu, China, in 2015, and the M.S. degree in electronic and communication engineering from Xidian University, Xi'an, China, in 2019. She is currently working toward the Ph.D. degree with the Engineering Product Development Pillar, Singapore University of Technology and Design, Singapore. Her research interests include reconfigurable intelligent surfaces and signal processing for wireless communications.

Chongwen Huang (Member, IEEE) received the B.Sc. degree from Nankai University, Tianjin, China, in 2010, the M.Sc. degree from the University of Electronic Science and Technology of China, Chengdu, China, in 2013, and the Ph.D. degree from the Singapore University of Technology and Design (SUTD), Singapore, in 2019. From October 2019 to September 2020, he is a Postdoc with SUTD. Since September 2020, he has been with Zhejiang University, Hangzhou, China, as a tenure-track young Professor. His main research interests include holographic

MIMO surface/reconfigurable intelligent surface, B5G/6G wireless communication, mmWave/THz communications, and deep learning technologies for wireless communications. Dr. Huang was the recipient of IEEE Marconi Prize Paper Award in Wireless Communications, and IEEE ComSoc Asia-Pacific Outstanding Young Researcher Award in 2021. He has been the Editor of IEEE COMMUNICATIONS LETTER, *Elsevier Signal Processing*, *EURASIP Journal on Wireless Communications and Networking*, and *Physical Communication* since 2021.

George C. Alexandropoulos (Senior Member, IEEE) received the Engineering Diploma, M.A.Sc., and Ph.D. degrees in computer engineering and informatics from the the School of Engineering, University of Patras, Patras, Greece, in 2003, 2005, and 2010, respectively. He has held research positions at various Greek universities and research institutes, and also with Mathematical and Algorithmic Sciences Lab, Paris Research Center, Huawei Technologies France. He is currently an Assistant Professor with the Department of Informatics and Telecommunications, School of Sciences, National and Kapodistrian University of Athens, Zografou, Greece. He is a Consultant for the Technology Innovation Institute, Abu Dhabi, UAE. His research interests include algorithmic design and performance analysis for wireless networks with emphasis on multiantenna transceiver hardware architectures, active and passive reconfigurable metasurfaces, integrated communications and sensing, millimeter wave and THz communications, and also distributed machine learning algorithms. He is also the Editor of IEEE WIRELESS COMMUNICATIONS LETTERS, *Elsevier Computer Networks*, *Frontiers in Communications and Networks*, and the *ITU Journal on Future and Evolving Technologies*. In the past, he has held various fixed-term and guest editorial positions with IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS and IEEE COMMUNICATIONS LETTERS, and also for various special issues at IEEE journals. Prof. Alexandropoulos is a Senior Member of the IEEE Communications, Signal Processing, and Information Theory Societies and also a registered Professional Engineer of the Technical Chamber of Greece. He is also a Distinguished Lecturer of the IEEE Communications Society. He has participated and/or technically managed more than ten European Union (EU) research and innovation projects, and several Greek and international research projects. He is currently NKUA's Principal Investigator of the EU H2020 RISE-6 G research and Innovation Project dealing with RIS-empowered smart wireless environments. He was the recipient of the Best Ph.D. Thesis Award 2010, IEEE Communications Society Best Young Professional in Industry Award 2018, EURASIP Best Paper Award of the Journal on Wireless Communications and Networking 2021, IEEE Marconi Prize Paper Award in Wireless Communications 2021, and Best Paper Award from the IEEE GLOBECOM 2021.

Wei E. I. Sha (Senior Member, IEEE) received the B.S. and Ph.D. degrees in electronic engineering from Anhui University, Hefei, China, in 2003 and 2008, respectively. From July 2008 to July 2017, he was a Postdoctoral Research Fellow and then a Research Assistant Professor with the Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong. From March 2018 to March 2019, he was a Marie-Curie Individual Fellow with University College London, London, U.K. In October 2017, he joined the College of Information

Science and Electronic Engineering, Zhejiang University, Hangzhou, China, where he is currently a tenure-tracked Assistant Professor. He has authored or coauthored 170 refereed journal articles, 140 conference publications, eight book chapters, and two books. His Google Scholar citation is 7288 with H-index of 43. His research interests include theoretical and computational research in electromagnetics, focusing on the multiphysics and interdisciplinary research. He was a reviewer for 60 technical journals and a technical program committee member of ten IEEE conferences. In 2015, he was awarded the Second Prize of Science and Technology from Anhui Province Government, China. He was also the recipient of six best student paper prizes and one Young Scientist Award with his students. He was an Associate Editor for IEEE JOURNAL ON MULTISCALE AND MULTIPHYSICS COMPUTATIONAL TECHNIQUES, IEEE OPEN JOURNAL OF ANTENNAS AND PROPAGATION, and IEEE ACCESS.

Zhaoyang Zhang (Senior Member, IEEE) received the Ph.D. degree from Zhejiang University, Hangzhou, China, in 1998. He is currently a Qishi Distinguished Professor with Zhejiang University. He has coauthored more than 400 peer-reviewed international journal and conference papers, including eight conference best papers awarded by IEEE ICC 2019 and IEEE Globecom 2020. His research interests are mainly include the fundamental aspects of wireless communications and networking, such as information theory and coding theory, network signal processing, and distributed learning, AI-empowered communications and networking, and synergetic sensing, computing and communication.

Dr. Zhang is/was the Editor of IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS, IEEE TRANSACTIONS ON COMMUNICATIONS, and *IET Communications*, and the General Chair, TPC Co-Chair or Symposium Co-Chair of PIMRC 2021 Workshop on Native AI Empowered Wireless Networks, VTC-Spring 2017 Workshop on HMWC, WCSP 2013 / 2018, and Globecom 2014 Wireless Communications Symposium. He was also a Keynote Speaker of IEEE Globecom 2021 Workshop on Native-AI Wireless, APCC 2018, and VTC-Fall 2017 Workshop on NOMA. He was awarded the National Natural Science Fund for Distinguished Young Scholar by NSFC in 2017.

Mérouane Debbah (Fellow, IEEE) received the M.Sc. and Ph.D. degrees from the Ecole Normale Supérieure Paris-Saclay, Cachan, France. He is currently a Chief Researcher with Technology Innovation Institute, Abu Dhabi, UAE. He is also an Adjunct Professor with the Department of Machine Learning, Mohamed Bin Zayed University of Artificial Intelligence, Abu Dhabi, UAE. From 1999 to 2002, he was with Motorola Labs, Saclay, France, and also with the Vienna Research Center for Telecommunications, Vienna, Austria, till 2003. From 2003 to 2007, he

was an Assistant Professor with Mobile Communications Department, Institut Eurecom, Sophia Antipolis, France. In 2007, he was appointed Full Professor with CentraleSupélec, Gif-sur-Yvette, France. From 2007 to 2014, he was the Director of the Alcatel-Lucent Chair on Flexible Radio. From 2014 to 2021, he was the Vice-President of the Huawei France Research Center. He was jointly the Director of the Mathematical and Algorithmic Sciences Lab and also the Director of the Lagrange Mathematical and Computing Research Center. Since 2021, he has been leading the AI and Digital Science Research Centers with the Technology Innovation Institute. He has managed eight EU projects and more than 24 national and international projects. His research interests include fundamental mathematics, algorithms, statistics, information, and communication sciences research. He is a WWRF Fellow, a Eurasisp Fellow, an AAIA Fellow, an Institut Louis Bachelier Fellow, and a Membre émérite SEE. He was the recipient of the ERC Grant MORE (Advanced Mathematical Tools for Complex Network Engineering) from 2012 to 2017, Mario Boella Award in 2005, IEEE Glavieux Prize Award in 2011, Qualcomm Innovation Prize Award in 2012, 2019 IEEE Radio Communications Committee Technical Recognition Award, and 2020 SEE Blondel Medal. He was the recipient of more than 20 Best Paper Awards, among which the 2007 IEEE GLOBECOM Best Paper Award, Wi-Opt 2009 Best Paper Award, 2010 Newcom++ Best Paper Award, WUN CogCom Best Paper 2012 and 2013 Award, 2014 WCNC Best Paper Award, 2015 ICC Best Paper Award, 2015 IEEE Communications Society Leonard G. Abraham Prize, 2015 IEEE Communications Society Fred W. Ellersick Prize, 2016 IEEE Communications Society Best Tutorial Paper Award, 2016 European Wireless Best Paper Award, 2017 Eurasisp Best Paper Award, 2018 IEEE Marconi Prize Paper Award, 2019 IEEE Communications Society Young Author Best Paper Award, 2021 Eurasisp Best Paper Award, 2021 IEEE Marconi Prize Paper Award, 2022 IEEE Communications Society Outstanding Paper Award, 2022 ICC Best Paper Award, and also Valuetools 2007, Valuetools 2008, CrownCom 2009, Valuetools 2012, SAM 2014, and 2017 IEEE Sweden VT-COM-IT Joint Chapter Best Student Paper Awards. He is an Associate Editor-in-Chief of the journal *Random Matrix: Theory and Applications*. He was an Associate Area Editor and Senior Area Editor of IEEE TRANSACTIONS ON SIGNAL PROCESSING from 2011 to 2013 and from 2013 to 2014, respectively. From 2021 to 2022, he was an IEEE Signal Processing Society Distinguished Industry Speaker.

Chau Yuen (Fellow, IEEE) received the B.Eng. and Ph.D. degrees from Nanyang Technological University (NTU), Singapore, in 2000 and 2004, respectively. He was a Postdoctoral Fellow with Lucent Technologies Bell Labs, Murray Hill, in 2005, and a Visiting Assistant Professor with The Hong Kong Polytechnic University, Hong Kong, in 2008. From 2006 to 2010, he was with the Institute for Infocomm Research (I2R), Singapore. Since 2010, he has been with the Singapore University of Technology and Design, Singapore. Dr. Yuen was the recipient of the

Lee Kuan Yew Gold Medal, Institution of Electrical Engineers Book Prize, Institute of Engineering of Singapore Gold Medal, Merck Sharp and Dohme Gold Medal, and twice the recipient of the Hewlett Packard Prize. He was also the recipient of the IEEE Asia Pacific Outstanding Young Researcher Award in 2012 and IEEE VTS Singapore Chapter Outstanding Service Award on 2019. He was the Editor of IEEE TRANSACTIONS ON COMMUNICATIONS and IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY, where he was awarded as the Top Associate Editor from 2009 to 2015. He was the Guest Editor of several special issues, including IEEE JOURNAL ON SELECTED AREAS IN COMMUNICATIONS, *IEEE Communications Magazine*, and IEEE TRANSACTIONS ON COGNITIVE COMMUNICATIONS AND NETWORKING. He is a Distinguished Lecturer of IEEE Vehicular Technology Society.
